

Front-end Take-Home — Apsu Home Page

Deliver a GitHub repo · AI tools allowed

Implement [the design](#) (desktop + mobile) as a React component library + page.

1. Tech stack

- Next.js (App Router) + React + TypeScript (strict) + Tailwind CSS; commit the lockfile
- Everything else — design tokens, image and icon handling, state management, routing, how you shape the API contracts and the data layer — is your call.

2. Directory

No prescribed structure — how you organize the codebase is itself part of the assessment. Explain your structure in the README.

3. Data (there are no API docs)

The backend does not exist yet. You design the data shapes for all dynamic content — they are the future API contract — and provide mock data conforming to them, standing in for the backend. We read the types first.

4. Required

A. Full-page fidelity. Every section, desktop + mobile, default state, faithful to the design at the two board widths (375 / 1440) — after your documented fixes under C.

B. Responsive floor. At **every** width from 320 to 1920 the page stays intact: no horizontal overflow, no wrapped nav items, no overlapping or clipped content. Pixel fidelity is only judged at the two boards; this clause is about integrity, not fidelity.

Bonus: graceful adaptation between and beyond the boards is a plus — how you achieved it will be discussed at the defense.

C. Design-flaw fixes. The design contains genuine mistakes — copy typos, questionable UI. Where you judge the design wrong, fix it, and log every deviation in the README (what you changed, why).

D. Interaction states & motion. Every interactive element needs hover / focus / pressed states and transition animations — follow the design where it specifies them, and your own UI/UX judgment where it is silent (the file has no hover designs; you design them). Consistency and restraint count more than quantity. List self-designed states in the README.

E. Storybook. Every stateful component gets one story per state — which components and which states is your call; we walk them one by one.

5. README

Must include the following — the rest is up to you:

- Which AI tools did you use, and which parts did they write? (Point to the corresponding conversation logs — see §6.)
- **Deviation log:** every design fix (C) and every self-designed interaction state (D) — what and why.

6. Submission & acceptance

Submit a GitHub repo link. **Keep your full commit history — do not squash; history is part of the submission.**

If you used AI tools, the conversation logs are part of the submission: include the complete, unedited session records for this project (e.g. Claude Code session transcripts, Cursor / ChatGPT exports) in the repo under `ai-logs/`. Logs may be sampled and discussed at the defense; using AI is fine — undisclosed or unreproducible AI use is not.

We will run:

```
npm install
npm run build      # passes
npm run dev        # compare against the Figma; resize 320–1920
npm run storybook  # walk components state by state
```
